# Le brûlage in-situ : une source importante de polluants atmosphériques

- Comme les feux industriels, brûlages de torchères, ou même les feux de forêts, le brûlage in-situ est à l'origine d'émissions dans l'atmosphère de quantités massives de polluants atmosphériques.
- L'impact environnemental et sanitaire dépend de la localisation du feu, des conditions de brûlage, des conditions météorologiques mais influence toujours la qualité de l'air

# Quels sont les polluants émis

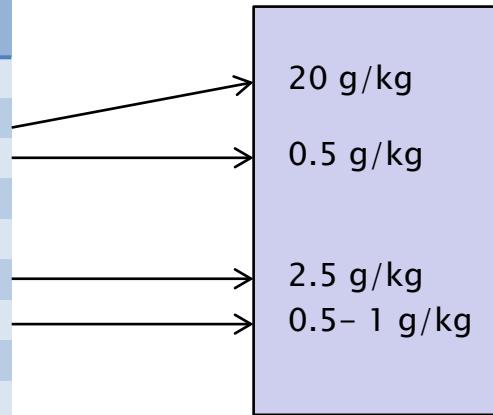

- Oxydes d'azotes
- Particules (PM10 et PM2.5)
- Dioxyde de soufre
- hydrocarbures (VOC)
- Hydrocarbures aromatiques polycycliques (PAHs)
- dioxines

(adapted from SL Ross Environmental Research Ltd, 2010).

(adapted from Tennyson, 1994, Buist, 1999)

Constituent	Quantity Emitted <sup>b</sup> (g emission/kg oil burned)
Carbon Dioxide (CO <sub>2</sub> )	3000
Particulate Matter (PM)	50 – 200 <sup>c,d</sup>
Elemental Carbon (EC)	4 – 10 <sup>e</sup>
Organic Carbon (OC)	45 – 90 <sup>e</sup>
Carbon Monoxide (CO)	20 – 50
Nitrogen Oxides (NOx)	1
Sulfur Dioxide (SO <sub>2</sub> )	3 <sup>e</sup>
Volatile Organic Compounds (VOC)	5
Polynuclear Aromatic Hydrocarbons (PAH)	0.004

<sup>a</sup>Updated from Buist et al., 1994, based on the Kuwait pool fire (Allen and Ferek, 1993) and the NOBE data (Ross et al., 1996)

<sup>b</sup>Quantities will vary with burn efficiency and composition of parent oil.

<sup>c</sup>For crude oils soot yield = 4 + 3 lg(fire diameter); yield in mass %, fire diameter in cm (Fraser et al., 1997)

<sup>d</sup>Estimates published by Environment Canada are considerably lower, ca. 0.2% to 3% for crude oil (Fingas, 1996)

<sup>e</sup>from Ross et al., 1996

Facteurs d'émission associés aux feux de forêts,  
d'après Turquety et al, 2013

## ISB versus other types of emissions

- Total PM10 emission during DWH : **40 Kton**
- Total PM10 emission in the USA : 600Kton
- Buncefield PM10 emissions : 10Kton
- Total black carbon released during DWH: **100-200 Ktons**
- Total elemental carbon : 8000 Kton during the Kuwait fires
- CO emissions during DWH :  **$10^4$  tons**
- CO emissions during the 2010 russian forest fires:  $19 \times 10^6$ – $33 \times 10^6$  tons

# EU Air quality standards ( AQ Directive)

Pollutants	AQ Directive 2008/50/EC
PM10	50 µg/m <sup>3</sup> daily average not exceeded more than 35 fois/year 40 µg/m <sup>3</sup> yearly average
PM2.5	Exposure index based on the daily average 25 µg/m <sup>3</sup> yearly average (20µg/m <sup>3</sup> in 2020)
O3	120 µg/m <sup>3</sup> 8-hours average not exceeded more than 25 days/year
NO2	40 µg/m <sup>3</sup> yearly average 200 µg/m <sup>3</sup> hourly average not exceeded more than 18 times/year
SO2	350 µg/m <sup>3</sup> , hourly average not exceeded more than 18 times/year 125 µg/m <sup>3</sup> daily average not exceeded more than 5 fois/year
Lead (Pb)	0.5 µg/m <sup>3</sup> yearly average
Benzene (C <sub>6</sub> H <sub>6</sub> )	5 µg/m <sup>3</sup> yearly average
CO	10 mg/m <sup>3</sup> maximum 8-hours daily average

# US Air quality standards (Clean Air Act)

Pollutant	Primary/Secondary	Averaging time	Level	Form
Carbon Monoxide (CO)	Primary	8 hour	9 ppm	Not to be exceeded more than once per year
		1 hour	35 ppm	
Lead (Pb)	Primary and secondary	Rolling 3 month average	0.15 $\mu\text{g m}^{-3}$ <sup>(a)</sup>	Not to be exceeded
Nitrogen Dioxide ( $\text{NO}_2$ )	Primary	1 hour	100 ppb	98th percentile, averaged over 3 years
	Primary and secondary	1 year	53 ppb <sup>(b)</sup>	Annual Mean
Ozone ( $\text{O}_3$ )	Primary and secondary	8 hour	75 ppb <sup>(c)</sup>	Annual fourth-highest daily maximum 8-hr concentration, averaged over 3 years
Particles $\text{PM}_{2.5}$	Primary	1 year	12 $\mu\text{g m}^{-3}$	Annual mean, averaged over 3 years
	secondary		15 $\mu\text{g m}^{-3}$	
	Primary and secondary	24 hours	35 $\mu\text{g m}^{-3}$	98th percentile, averaged over 3 years
Particles $\text{PM}_{10}$	Primary and secondary	24 hours	150 $\mu\text{g m}^{-3}$	Not to be exceeded more than once per year on average over 3 years
Sulfur Dioxide ( $\text{SO}_2$ )	Primary	1 hour	75 ppb <sup>(d)</sup>	99th percentile of 1-hour daily maximum concentrations, averaged over 3 years
	Secondary	24 hours	0.5 ppm	Not to be exceeded more than once per year

(a) Final rule signed October 15, 2008. The 1978 lead standard (1.5  $\mu\text{g/m}^3$  as a quarterly average) remains in effect until one year after an area is designated for the 2008 standard, except that in areas designated nonattainment for the 1978, the 1978 standard remains in effect until implementation plans to attain or maintain the 2008 standard are approved.

(b) The official level of the annual  $\text{NO}_2$  standard is 0.053 ppm, equal to 53 ppb, which is shown here for the purpose of clearer comparison to the 1-hour standard.

(c) Final rule signed March 12, 2008. The 1997 ozone standard (0.08 ppm, annual fourth-highest daily maximum 8-hour concentration, averaged over 3 years) and related implementation rules remain in place. In 1997, EPA revoked the 1-hour ozone standard (0.12 ppm, not to be exceeded more than once per year) in all areas, although some areas have continued obligations under that standard ("anti-backsliding"). The 1-hour ozone standard is attained when the expected number of days per calendar year with maximum hourly average concentrations above 0.12 ppm is less than or equal to 1.

(d) Final rule signed June 2, 2010. The 1971 annual and 24-hour  $\text{SO}_2$  standards were revoked in that same rulemaking. However, these standards remain in effect until one year after an area is designated for the 2010 standard, except in areas designated nonattainment for the 1971 standards, where the 1971 standards remain in effect until implementation plans to attain or maintain the 2010 standard are approved.

# Evaluer l'impact sanitaire de l'in-situ burning

- Critère généralement utilisé : respect des normes de qualité de l'air, notamment pour les particules (PM10 et PM2.5)
- Besoin d'évaluer l'impact du panache sur les concentrations de polluants atmosphériques dans les zones potentiellement impactées pour limiter l'exposition des populations
- Possibilité de réaliser de campagnes de mesures pour surveiller la qualité de l'air pendant les opérations
- Mise en œuvre de modèle pour prédire les effets et les distances « de sécurité ». Exemple : table établie à partir de simulations du logiciel ALOFT

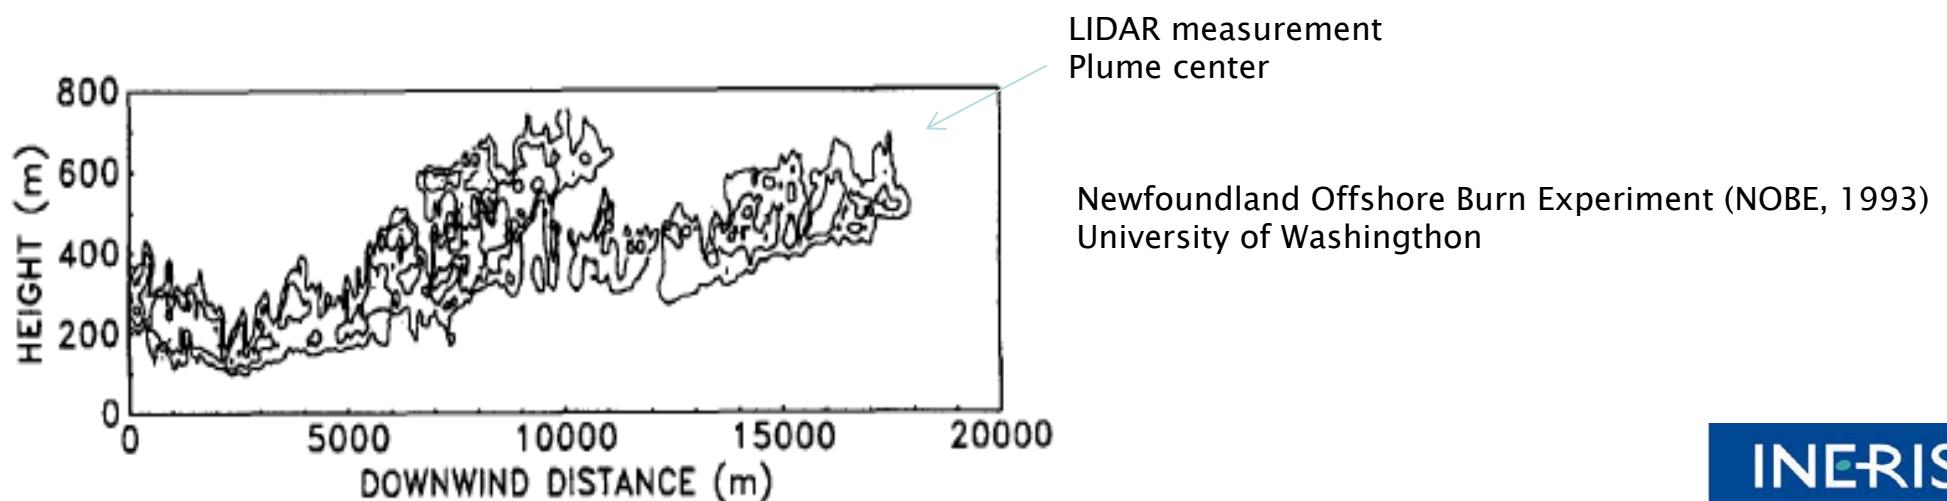

Location of Fire	Green Zone	Yellow Zone	Red Zone
Flat terrain on land			
Water <3 miles from shore	>3 miles	1 to 3 miles	<1 mile
Water >3 miles from shore	>1 mile	not applicable	<1 mile

1 mile = 1.6 km

Distance de sécurité entre les feux et les populations sous le vent, d'après le guide ARRT (Alaska Regional response Team)

# Marine conditions for atmospheric dispersion

- Atmospheric dispersion is driven by the nature of the surface. Sea surface implies different dispersion conditions compared to soils
  - Lower boundary layer heights (more stable conditions), the sea surface temperature being lower than the temperature in the air
  - Stable conditions when burning
  - High relative humidity
  - Presence of sea salts (potential interactions but not studied so far)
  - Sea temperature drives the air temperature (min temperature in March, max in September)
- In certain areas (Artic region) the temperature of the sea can lead to high gradients with the atmosphere, with very low boundary layer heights

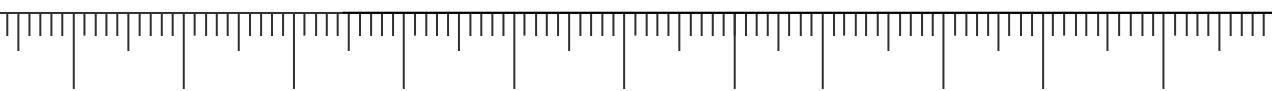

# Evaluer l'impact sanitaire de l'in-situ burning

- Critère généralement utilisé : respect des normes de qualité de l'air, notamment pour les particules (PM10 et PM2.5)
- Besoin d'évaluer l'impact du panache sur les concentrations de polluants atmosphériques dans les zones potentiellement impactées pour limiter l'exposition des populations
- Possibilité de réaliser de campagnes de mesures pour surveiller la qualité de l'air pendant les opérations
- Mise en œuvre de modèle pour prédire les effets et les distances « de sécurité ». Exemple : table établie à partir de simulations du logiciel ALOFT

Location of Fire	Green Zone	Yellow Zone	Red Zone
Flat terrain on land			
Water <3 miles from shore	>3 miles	1 to 3 miles	<1 mile
Water >3 miles from shore	>1 mile	not applicable	<1 mile

1 mile = 1.6 km

## Etude de sensibilité

**Scenario #1: Alaska coast (60°48"36'N / 146°52"23'W)**

**Date of spill :** 09/11/2014 07:30:00

**Water temperature :** 8°C

**Scenario #2: Gulf of Mexico (28°11"59'N / 88°47"59'W)**

**Date of spill:** 14/09/2014 11:00:00

**Water temperature :** 20°C

**Scenario #3: West African Coast (3° 01' N / 6° 58' E)**

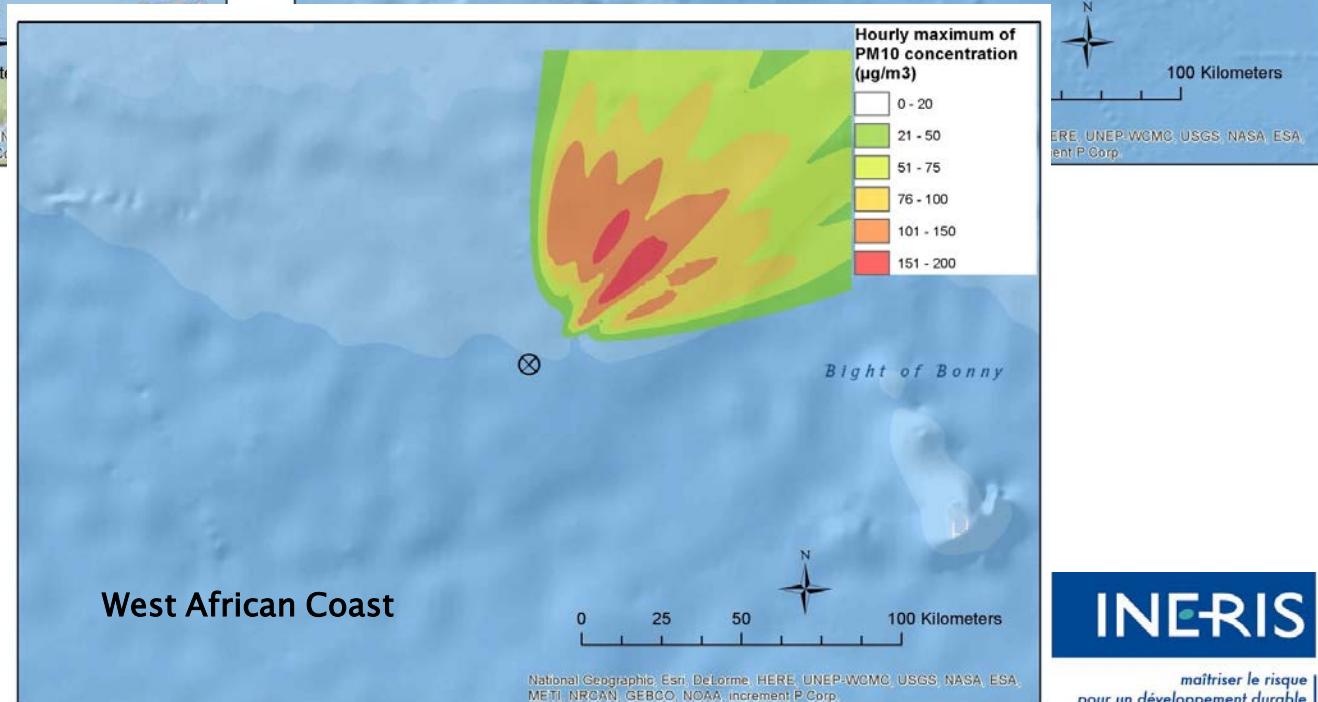

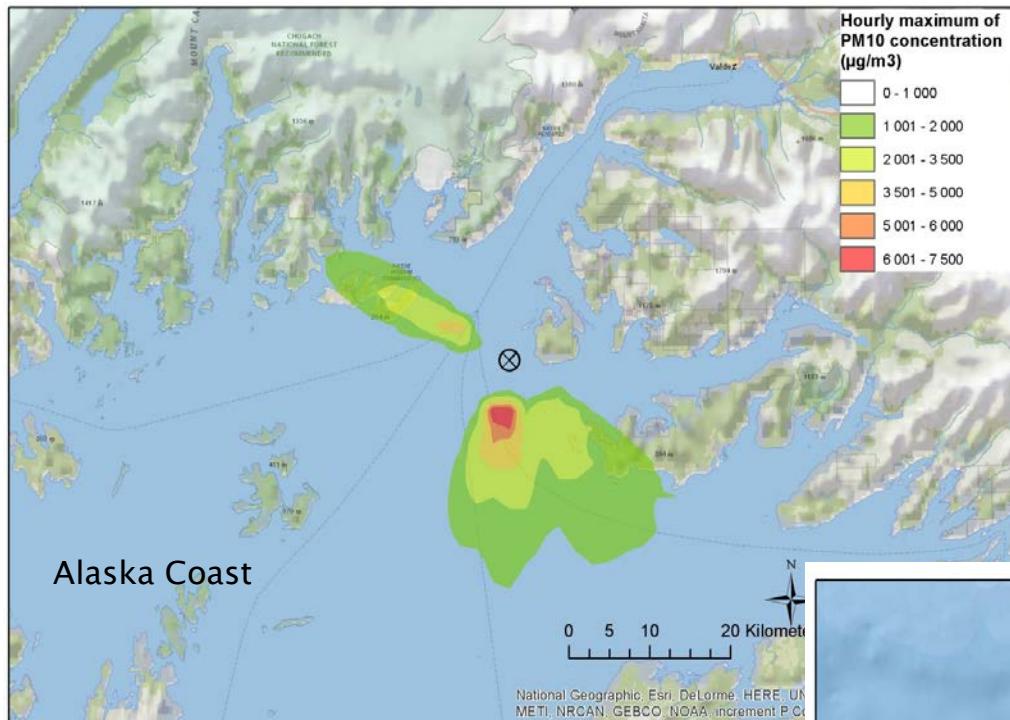

**Date of spill :** 09/11/2014 07:00:00

**Water temperature:** 28°C

7 days of simulation; same source term

Gaussian model : ADMS run by INERIS

# Results: maximum hourly PM10 concentrations

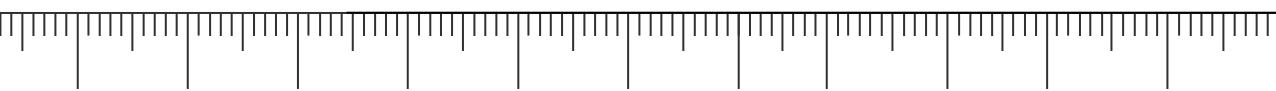

## Analyse :

- Une certaine variabilité dans les résultats qui ne permet pas d'assurer la validité des distances de sécurité tabulées par ARRT
- Grande sensibilité aux conditions météorologiques, les précipitations et la température de l'eau
- Pas de simulation des transformations chimiques, bien que :
  - Massive release of VOC can impact ozone concentrations of ozone concentrations downwind the plume
  - For the same reason ISB can favour secondary organic aerosol formation, and therefore increase PM concentrations
  - Long range transport of a pollutants in the plume is a main driver

# Conclusions

- Relativement peu d'études d'impact du brûlage in-situ sur la qualité de l'air : plutôt réalisées avec des modèles simples en vue d'une évaluation des distances d'impact.

Name	Type of study	Modelling tools	Reference
Deepwater Horizon (2010)	Risk assessment levels due to dioxine (PCDD/PCDF) emission	Plume model (AERMOD) + Regional study using HYSPLIT model in an eulerian/puff mode - plume rise computation from OBODM (Dumbauld et al. (1973) derivation of Briggs formula (1971), for large source)	Schaum et al., 2012

NOBE, ALASKA and MOBILE	Trajectory and particle concentration simulation	Sum - up of previous papers + comparison with CALPUFF	Mc Grattan et al., 2003
Coastal measurement in California and Gulf of Mexico	Simulation of emissions from offshore sources, not specific to in-situ burning.	Plume model + specific adaptation for over sea emission and coastal environment	Hanna et al., 1985

- Mais il est difficile de qualifier l'impact du brûlage in-situ sur l'environnement sans prendre en compte des facteurs particulier liés à la localisation, les conditions météorologiques, voire la nature des produits brûlés
- Néanmoins certaines campagnes de brûlage instrumentées permettent d'accéder à de nouvelles données
  - Deepwater Horizon (DWH) oil spill : Middlebrook et al., 2011 predicted high Secondary Organic Aerosols along the coast
  - Impact of the evaporation of VOC on O<sub>3</sub> production (some papers)
- Importance potentielle des impacts des retombées de poussières, carbone suie (sur le continent Articque?), dioxines et HAPS à cause de leurs effets sur la santé. Le dépôt est faible en mer mais peut être significatif sur terre là où vivent les populations.
